

# **COP 3402 Systems Software**

---

## **Predictive Parsing (First and Follow Sets)**

# Outline

---

1. First Set
2. Nullable Symbols
3. Follow Set
4. Predictive Parsing Table
5. LL(1) Parsing

# First set

---

**A recursive descent (or predictive) parser chooses the correct production by looking a fixed number of symbols ahead (typically one symbol or token).**

## First set:

Let **X** be any string of grammar symbols (terminals and non-terminals).

**First(X)** is defined to be the set of terminals that begin strings derived from **X**.

# First set

---

Definition:  $\text{FIRST}(\mathbf{X}) = \{ \mathbf{t} \mid \mathbf{X} \Rightarrow^* \mathbf{tZ} \text{ for some } \mathbf{Z} \} \cup \{ \epsilon \mid \text{if } \mathbf{X} \Rightarrow^* \epsilon \}$

If  $X \rightarrow A B C$ , then  $\text{FIRST}(X) = \text{FIRST}(A B C)$  and is computed as follows:

A is a terminal

$$\text{FIRST}(X) = \text{FIRST}(A B C) = \{A\}$$

For instance, if  $X \rightarrow t B C$ , then

$$\text{FIRST}(X) = \text{FIRST}(t B C) = \{t\}$$

A is a non-terminal and A does not derive to  $\epsilon$

$$\text{FIRST}(X) = \text{FIRST}(A B C) = \text{FIRST}(A)$$

A is a non-terminal and A derives to  $\epsilon$

$$\text{FIRST}(X) = \text{FIRST}(A B C) = \text{FIRST}(A) - \{ \epsilon \} \cup \text{FIRST}(BC)$$

Similarly, for  $\text{FIRST}(BC)$  we have:

B is a terminal

$$\text{FIRST}(BC) = \{B\}$$

B is a non-terminal and B does not derive to  $\epsilon$

$$\text{FIRST}(BC) = \text{FIRST}(B)$$

B is a non-terminal and B derives to  $\epsilon$

$$\text{FIRST}(BC) = \text{FIRST}(B) - \{ \epsilon \} \cup \text{FIRST}(C)$$

And so on...

# First set

---

Example:

$S \rightarrow A B C \mid C b B \mid B a$

$A \rightarrow d a \mid B C$

$B \rightarrow g \mid \epsilon$

$C \rightarrow h \mid \epsilon$

$\text{FIRST}(S) = \text{FIRST}(A B C) \cup \text{FIRST}(C b B) \cup \text{FIRST}(B a)$

$\text{FIRST}(A) = \text{FIRST}(d a) \cup \text{First}(B C) = \{ d \} \cup \text{FIRST}(B C)$

$\text{FIRST}(B) = \text{FIRST}(g) \cup \text{First} \{ \epsilon \} = \{ g, \epsilon \}$

$\text{FIRST}(C) = \text{FIRST}(h) \cup \text{First} \{ \epsilon \} = \{ h, \epsilon \}$

Now we can compute:

$\text{FIRST}(BC) = \text{FIRST}(B) - \{ \epsilon \} \cup \{ h, \epsilon \} = \{ g, \epsilon \} - \{ \epsilon \} \cup \{ h, \epsilon \} = \{ g, h, \epsilon \}$

and

$\text{FIRST}(A) = \{ d \} \cup \{ g, h, \epsilon \} = \{ d, g, h, \epsilon \}$

Exercise: Compute  $\text{FIRST}(C b B)$  and  $\text{FIRST}(B a)$  in order to compute  $\text{FIRST}(S)$

# First set

---

Example: Given the following expression grammar:

$$\begin{aligned} E &\rightarrow E + T \mid T \\ T &\rightarrow T * F \mid F \\ F &\rightarrow ( E ) \mid \text{id} \end{aligned}$$

$$\text{First}(E + T) = \{ \text{id}, ( \}$$

$$\begin{aligned} \text{Because: } E + T &\rightarrow T + T \rightarrow F + T \rightarrow \text{id} + T \\ E + T &\rightarrow T + T \rightarrow F + T \rightarrow ( E ) + T \end{aligned}$$

$$\text{First}(E ) = \{ \text{id}, ( \}$$

$$\begin{aligned} \text{Because: } E &\rightarrow T \rightarrow F \rightarrow \text{id} \\ E &\rightarrow T \rightarrow F \rightarrow ( E ) \end{aligned}$$

# Nullable Symbols

---

Nullable symbols those that produce the empty ( $\epsilon$ ) string.

Example: Given the following grammar, find the nullable symbols and the FIRST sets:

$Z \rightarrow d$                        $Y \rightarrow \epsilon$                        $X \rightarrow Y$

$Z \rightarrow X Y Z$                        $Y \rightarrow c$                        $X \rightarrow a$

Note that if X can derive the empty string, nullable( X ) is true.

$X \rightarrow Y \rightarrow \epsilon$

$Y \rightarrow \epsilon$

$Z \rightarrow d$

$Z \rightarrow X Y Z$

	Nullable	First
X	Yes	{ a, c, $\epsilon$ }
Y	Yes	{ c, $\epsilon$ }
Z	No	{ a, c, d }

# Follow set

---

$$\text{FOLLOW}(\mathbf{A}) = \{ \mathbf{t} \mid \mathbf{S} \Rightarrow^* \alpha \mathbf{A} \mathbf{t} \omega \text{ for some } \alpha, \omega \}$$

Given a non-terminal  $\mathbf{A}$ ,  $\text{FOLLOW}(\mathbf{A})$  is the set of terminal symbols that can immediately follow  $\mathbf{A}$ .

Example 1: If there is a derivation containing  $\mathbf{A} \mathbf{t}$ , then  $\mathbf{t}$  is in  $\text{FOLLOW}(\mathbf{A}) = \mathbf{t}$ .

Example 2: If there is a derivation containing  $\mathbf{A} \mathbf{B} \mathbf{C} \mathbf{t}$  and  $\mathbf{B}$  and  $\mathbf{C}$  are nullable, then  $\mathbf{t}$  is in  $\text{FOLLOW}(\mathbf{A})$ .

Example 3: The FIRST / FOLLOW sets and nullable symbols for the following grammar are:

$\mathbf{Z} \rightarrow \mathbf{d}$	$\mathbf{Y} \rightarrow \epsilon$	$\mathbf{X} \rightarrow \mathbf{Y}$
$\mathbf{Z} \rightarrow \mathbf{X} \mathbf{Y} \mathbf{Z}$	$\mathbf{Y} \rightarrow \mathbf{c}$	$\mathbf{X} \rightarrow \mathbf{a}$

	Nullable	FIRST	FOLLOW
X	Yes	{ a, c, $\epsilon$ }	{ a, c, d }
Y	Yes	{ c, $\epsilon$ }	{ a, c, d }
Z	No	{ a, c, d }	{ }

# Predictive parsing table

## Method to construct the predictive parsing table

For each production  $A \rightarrow \alpha$  of the grammar, do the following:

1. Add  $A \rightarrow \alpha$  to  $m[A, t]$  for each terminal  $t$  in  $\text{FIRST}(\alpha)$ .
2. If  $\text{nullable}(\alpha)$  is true, add  $A \rightarrow \alpha$  to  $m[A, t]$  for each  $t$  in  $\text{FOLLOW}(A)$ .

Example: Given the grammar:

$Z \rightarrow d$	$Y \rightarrow \epsilon$	$X \rightarrow Y$
$Z \rightarrow XYZ$	$Y \rightarrow c$	$X \rightarrow a$

	a	c	d
X	$X \rightarrow a$ $X \rightarrow Y$	$X \rightarrow Y$	$X \rightarrow Y$
Y	$Y \rightarrow \epsilon$	$Y \rightarrow c$ $Y \rightarrow \epsilon$	$Y \rightarrow \epsilon$
Z	$Z \rightarrow XYZ$	$Z \rightarrow XYZ$	$Z \rightarrow d$ $Z \rightarrow XYZ$

$m[Y, d]$  (points to the circled  $Y \rightarrow \epsilon$  in the table)

← Table m

# Predictive parsing table

**Example: Given the grammar:**

$S \rightarrow E\$$

$E \rightarrow E + T$

$E \rightarrow T$

$T \rightarrow T * F$

$T \rightarrow F$

$F \rightarrow \text{id}$

$F \rightarrow ( E )$

We can rewrite the grammar to avoid left recursion obtaining thus:

$S \rightarrow E\$$

$E \rightarrow T E'$

$E' \rightarrow + T E'$

$E' \rightarrow \epsilon$

$T \rightarrow F T'$

$T' \rightarrow * F T'$

$T' \rightarrow \epsilon$

$F \rightarrow \text{id}$

$F \rightarrow ( E )$

Compute First, Follow, and nullable.

	Nullable	First	Follow
E	No	{ <b>id</b> , ( }	{ <b>)</b> , \$ }
E'	Yes	{ <b>+</b> , $\epsilon$ }	{ <b>)</b> , \$ }
T	No	{ <b>id</b> , ( }	{ <b>)</b> , <b>+</b> , \$ }
T'	Yes	{ <b>*</b> , $\epsilon$ }	{ <b>)</b> , <b>+</b> , \$ }
F	No	{ <b>id</b> , ( }	{ <b>)</b> , <b>*</b> , <b>+</b> , \$ }

# Predictive parsing table

Parsing table for the expression grammar:

	+	*	id	(	)	\$
E			$E \rightarrow T E'$	$E \rightarrow T E'$		
E'	$E' \rightarrow + T E'$					$E' \rightarrow \epsilon$ $E' \rightarrow \epsilon$
T			$T \rightarrow F T'$	$T \rightarrow F T'$		
T'	$T' \rightarrow \epsilon$	$T' \rightarrow * F T'$			$T' \rightarrow \epsilon$ $T' \rightarrow \epsilon$	
F			$F \rightarrow id$	$F \rightarrow ( E )$		

# Predictive parsing table

---

Using the predictive parsing table, it is easy to write a recursive-descent parser:

	+	*	id	(	)
T'	$T' \rightarrow \varepsilon$	$T' \rightarrow *FT'$			$T' \rightarrow \varepsilon$

```
void Tprime() {  
    switch (token) {  
        case PLUS : break ;  
        case TIMES : accept(TIMES) ; F() ; Tprime(); break ;  
        case RPAREN : break ;  
        default : error() ;  
    }  
}
```

# Left factoring

---

Another problem that we must avoid in predictive parsers is when two productions for the same non-terminal start with the same symbol.

Example:  $S \rightarrow \text{if } E \text{ then } S$   
 $S \rightarrow \text{if } E \text{ then } S \text{ else } S$

Solution: Left-factor the grammar. Take allowable ending “**else S**” and  **$\epsilon$** , and make a new production (new non-terminal) for them:

$$\begin{aligned} S &\rightarrow \text{if } E \text{ then } S X \\ X &\rightarrow \text{else } S \\ X &\rightarrow \epsilon \end{aligned}$$

Grammars whose predictive parsing tables contain no multiples entries are called LL(1).

The first L stands for left-to-right parse of input string. (input string scanned from left to right)

The second L stands for leftmost derivation of the grammar

The “1” stands for one symbol lookahead

# Left Factoring

---

The following (unambiguous) grammar for arithmetic expressions is not LL(1):

```
E -> E + E | T
T -> T * F | F
F -> id | num | ( E )
```

We obtain an LL(1) by using a grammar transformation called left factoring:

```
E  -> T E'
E' -> + T E' | ε
T  -> F T'
T' -> * F T' | ε
F  -> id | num | ( E )
```

# Left Recursive Grammars

---

A grammar is called **left recursive** if there is a derivation  $A \rightarrow A a$  for some string  $a$  and some non-terminal symbol.

Left recursive grammars are not suitable for LL(k) parsers.

# Left Factoring

---

Left factoring is a grammar transformation that eliminates left recursion.

For example, the pair

$$A \rightarrow A a \mid b$$

could be replaced by the following two non-left-recursive productions:

$$\begin{aligned} A &\rightarrow b A' \\ A' &\rightarrow a A' \mid \epsilon \end{aligned}$$

# A Non-LL(1) Grammar

---

For instance, a grammar having a production such as

$$A \rightarrow a b_1 \mid a b_2$$

is not suitable for an LL(1) parser.

If the parser looks only one token ahead and sees the token **a**, then it cannot determine which choice of the alternation to follow.

# Left Factoring

---

Using again left factoring, the production

$$A \rightarrow a b_1 \mid a b_2$$

can be left-factored to the following two productions:

$$\begin{aligned} A &\rightarrow a A' \\ A' &\rightarrow b_1 \mid b_2 \end{aligned}$$

# Nonrecursive predictive parsing

**Example: Given the grammar:**

$$\begin{array}{lll} S \rightarrow E\$ & & \\ E \rightarrow TE' & T \rightarrow FT' & F \rightarrow \text{id} \\ E' \rightarrow +TE' & T' \rightarrow *FT' & F \rightarrow (E) \\ E' \rightarrow \epsilon & T' \rightarrow \epsilon & \end{array}$$

With the following First, Follow, and nullable.

	Nullable	First	Follow
S	No	{ id }	
E	No	{ id , ( }	{ ), \$ }
E'	Yes	{ + }	{ ), \$ }
T	No	{ id , ( }	{ ), +, \$ }
T'	Yes	{ * }	{ ), +, \$ }
F	No	{ id , ( }	{ ), *, +, \$ }

# Nonrecursive predictive parsing

	+	*	id	(	)	\$
E			$E \rightarrow TE'$	$E \rightarrow TE'$		
E'	$E' \rightarrow +TE'$				$E' \rightarrow \epsilon$	$E' \rightarrow \epsilon$
T			$T \rightarrow FT'$	$T \rightarrow FT'$		
T'	$T' \rightarrow \epsilon$	$T' \rightarrow *FT'$			$T' \rightarrow \epsilon$	$T' \rightarrow \epsilon$
F			$F \rightarrow id$	$F \rightarrow (E)$		

A nonrecursive predictive parser can also be implemented by using a stack instead of recursively calling procedures. This approach is called table driven.

To implement it we need:

- 1) As input a string “w”.
- 2) A parsing table.
- 3) A stack.

Initial configuration:

- 1) The string  $w\$$  in the input buffer
- 2) The start symbol S on top of the stack, above the end of file symbol \$.

# Nonrecursive predictive parsing

	+	*	id	(	)	\$
E			$E \rightarrow TE'$	$E \rightarrow TE'$		
E'	$E' \rightarrow +TE'$				$E' \rightarrow \epsilon$	$E' \rightarrow \epsilon$
T			$T \rightarrow FT'$	$T \rightarrow FT'$		
T'	$T' \rightarrow \epsilon$	$T' \rightarrow *FT'$			$T' \rightarrow \epsilon$	$T' \rightarrow \epsilon$
F			$F \rightarrow id$	$F \rightarrow (E)$		

STACK

INPUT

→  
\$E

←  
id + id \* id\$

↑  
Current input symbol(cis)

↑  
Top of stack symbol (X)

**Algorithm:**

```

push $ onto the stack
push start symbol E onto the stack

repeat { /*stack not empty */
    if (X == cis) {
        pop the stack;
        advance cis to next symbol;
    }
    elseif (X is terminal) error();
    elseif (M[X, cis] is error entry) error();
    elseif (M[X, cis] is production) {
        pop the stack;
        push the right hand side of
        the production in reverse order;
    }
    let X point to the top of the stack.
}
until (X == $);
    
```

# Nonrecursive predictive parsing

Stack	Input	Production	Algorithm:
\$E	id + id * id\$		push \$ onto the stack
\$E'T	id + id * id\$	$E \rightarrow TE'$	push start symbol E onto the stack
\$E'T'F	id + id * id\$	$T \rightarrow FT'$	repeat { /* stack not empty*/
\$E'T'id	id + id * id\$	$F \rightarrow id$	if (X == cis) {
\$E'T'	+ id * id\$	match id	pop the stack;
\$E'	+ id * id\$	$T' \rightarrow \epsilon$	advance cis to next symbol;
\$E'T+	+ id * id\$	$E' \rightarrow +TE'$	}
\$E'T	id * id\$	match +	elseif (X is terminal) error();
\$E'T'F	id * id\$	$T \rightarrow FT'$	elseif (M[X, cis] is error entry) error();
\$E'T'id	id * id\$	$F \rightarrow id$	elseif (M[X, cis] is production) {
\$E'T'	* id\$	match id	pop the stack;
\$E'T'F*	* id\$	$T' \rightarrow *FT'$	push the right hand side of
\$E'T'F	id\$	match *	the production in reverse order ;
\$E'T'id	id\$	$F \rightarrow id$	}
\$E'T'	\$	match id	let X point to the top of the stack.
\$E'	\$	$T' \rightarrow \epsilon$	}
\$	\$	$E' \rightarrow \epsilon$	until (X == \$);

To compute  $\text{FIRST}(X)$  for all grammar symbols  $X$ , apply the following rules until no more terminals or  $\epsilon$  can be added to any  $\text{FIRST}$  set.

1. If  $X$  is a terminal, then  $\text{FIRST}(X) = \{ X \}$ .
2. If  $X$  is a non-terminal and  $X \rightarrow Y$

# **COP 3402 Systems Software**
